Abstract

A genetic programming tool is proposed here for data classification. The tool is based on Grammatical Evolution technique and its designed to exploit multicore computing systems using the OpenMp library. The tool constructs classification programs in a C – like programming language in order to classify the input data, producing simple if – else rules and upon termination the tool produces the classification rules in C and Python files. The tool is tested on a wide range of classification problems and the produced results are compared against traditional techniques for data classification, yielding very promising results.

Keywords: Genetic algorithm, Data classification, Grammatical evolution, Stochastic methods

1. Introduction

- Data classification finds many applications on a series of practical prob-
- lems from areas such as chemistry [1, 2, 3], biology [4, 5], economics [6, 7],
- physics [8, 9] etc. During the past years many methods have been proposed to
- problems of this category such as neural networks [10], radial basis functions
- networks [11], support vector machines [12], etc. The proposed method,
- which is initially described in [13], constructs classification programs in a
- human readable format using the technique of Grammatical Evolution [14].
- Grammatical evolution is an evolutionary process that has been applied with
- success in many areas such as music composition [15], economics [16], sym-10
- bolic regression [17], robot control [18] and caching algorithms [23]. 11
- This article introduces a software tool (named GenClass) coded in ANSI 12
- C++, for data classification using classification rules in human readable form.
- The rules are created with the Grammatical evolution method and can be ap-
- plied in any classification problem, without a priory knowledge of the dataset.

Also, this tool has a series of command line options to control the various aspects of the software, such as mutation rate or number of chromosomes in the genetic population.

The rest of this article is organized as follows: in section 2 the software is described in detail, in section 3 a series of experiments on some well - known classification datasets are demonstrated, in section 4 the impact of the software tool is discussed and finally in section 5 conclusions and guidelines for further expansion of the software are presented.

2.1. The proposed algorithm

The main steps of the algorithm are:

1. **Initialization** step.

- (a) Read the train data
- (b) Set N_G the maximum number of generations, N_C as the number of chromosomes, P_S the selection rate, P_M the mutation rate.
- (c) Initialize the chromosomes of the population.

2. Genetic step

- (a) For $i = 1, ..., N_q$ do
 - i. Create for every chromosome in the population a classification program using Grammatical Evolution.
 - ii. Calculate the fitness for every chromosome of the population
 - iii. Execute the genetic operators of selection with rate P_S and mutation with rate P
- (b) EndFor

3. Evaluation step

- (a) Create a classification program for the best chromosome in the population.
- (b) Apply the previous program to test set and report the induced error.
- The installation of the software is explained in detail in the relevant Wiki page https://github.com/itsoulos/GenClass/wiki.

2.2. The executable genclass

The outcome of the software compilation and installation is the executable genclass under the directory bin. The executable has the following command line parameters:

- 1. -h:The program prints a help screen.
- 2. -c count: The parameter count determines the number of chromosomes with default value 500.
- 3. -f **count**. Specify fold count for fold validation. Default value 0 (no folding).
 - 4. -g **gens**: The parameter **gens** determines the maximum number of generations with default value is 200.
 - 5. -d **count**. The parameter d determines the maximum number of threads used by the OpenMp library. The default value is 16.
 - 6. -s srate: The parameter srate specifies the selection rate with default value 0.10 (10%).
- 7. -m mrate: The parameter mrate specifies the mutation rate with default value 0.05 (5%).
 - 8. -l size: The parameter size determines the size of every chromosome with default value 100.
 - 9. -p **train_file**: The string parameter **train_file** specifies the file containing the points that will be used as train data for the algorithm. The file should conform to the format outlined in figure 1.
 - 10. -t **test_file**: The string parameter **test_file** specifies the file containing the test data for the particular problem. The file should be in the same format as the **train_file**.
 - 11. -o **method**: The string parameter method specifies the output method for the executable. The available options are
 - (a) simple. The program prints output only on termination.
 - (b) csv. In every generation the program prints: number of generations, train error and test error.
 - (c) full. The program prints in every generation detailed information about the optimization procedure.
 - 12. -r seed: The integer parameter seed specifies the seed for the random number generator. It can assume any integer value.

81 2.3. The output files

The software produces upon termination two distinct files that contains the classification rules. The first file is written in ANSI C++ named classifier.c and an example is shown in Figure 2. The second file is written in Python named classifier.py and an example is displayed in Figure 3.

3. Experiments

3.1. A typical example

Consider the Ionosphere dataset available from the Machine Learning Repository. The ionosphere dataset contains data from the Johns Hopkins Ionosphere database. The dataset has been divided into two files, ionosphere.train and ionosphere.test under directory examples of the distribution. A typical run for the GenClass will be

93 ../bin/genclass —p ionosphere.train —t ionosphere.test —g 10 —o csv

The output of this command is shown in Figure 4.

121

In order to measure the efficiency of the proposed method a series of experiments were conducted on some common classification problems found in two major dataset databases:

- 99 1. UCI dataset repository, https://archive.ics.uci.edu/ml/index.
 100 php
 - 2. Keel repository, https://sci2s.ugr.es/keel/datasets.php[19].

All the experiments were conducted 30 times using different seed for the random generator each time and averages were taken. In all experiments we have used the parameters shown in table 1. The following datasets were used

- 1. Wine dataset. The wine recognition dataset contains data from wine chemical analysis.
- 2. Glass dataset. The dataset contains glass component analysis for glass pieces that belong to 6 classes.
- 3. **Tae** dataset. The data consist of evaluations of teaching performance for the University of Wisconsin-Madison.
- 4. **Spiral** dataset: The spiral artificial dataset contains 1000 two-dimensional examples that belong to two classes (500 examples each). The number of the features is 2. The data in the first class are created using the following formula: $x_1 = 0.5t \cos(0.08t)$, $x_2 = 0.5t \cos(0.08t + \frac{\pi}{2})$ and the second class data using: $x_1 = 0.5t \cos(0.08t + \pi)$, $x_2 = 0.5t \cos(0.08t + \frac{3\pi}{2})$
 - 5. **Pima** dataset. The Pima Indians Diabetes dataset contains with two categories: healthy and diabetic.
- 6. **Ionosphere** dataset. The ionosphere dataset (ION in the following tables) contains data from the Johns Hopkins Ionosphere database.
 - 7. Appendictis dataset, proposed in [20].

- 8. Australian, the dataset concerns credit card applications.
- 9. **Hayes roth** dataset. This dataset[21] contains **5** numeric-valued attributes and 132 patterns.
- 10. Alcohol, a dataset about Alcohol consumption [22].

122

142

143

144

145

150

- 11. **Dermatology**. Dataset used for differential diagnosis of erythematosquamous diseases.
- 12. **Balance**. This data set was generated to model psychological experimental results.
- 130 **Regions2** dataset. It is created from liver biopsy images of patients with hepatitis C [25].
- 14. **Parkinsons**. This dataset is composed of a range of biomedical voice measurements from 31 people, 23 with Parkinson's disease (PD)[24].
- 134 15. **Wdbc**. The Wisconsin diagnostic breast cancer dataset (WDBC) contains data for breast tumors.
- 16. **Popfailures**. This dataset contains records of simulation crashes encountered during climate model.
- 138 17. **Heart**. The task is to detect the absence or presence of heart disease.
- 18. **Ecoli**. The goal here is to predict the localization site of proteins.
- 19. **Haberman**. A dataset about breast cancer from a study at the University of Chicago's Billings Hospital.
 - 20. **HouseVotes**. This data set includes votes for each of the U.S. House of Representatives Congressmen on the 16 key votes.
 - 21. **Shuttle**. The task is to decide what type of control of a spacecraft should be employed.
- 146 22. **Lymography**. The aim here is to detect the presence of a lymphoma in patients.
- 148 23. Mammographic. This dataset be used to identify the severity (benign or malignant) of a mammographic mass lesion.
 - 24. OptDigits. Optical Recognition of Handwritten Digits data set.
- 151 25. **Page Blocks**. The dataset contains blocks of the page layout of a document that has been detected by a segmentation process.
- 153 26. **Penbased**. This is a Pen-Based Recognition of Handwritten Digits data set.
- 155 27. **Saheart**. The dataset is about to categorize persons if have a coronary heart disease.
- 28. **Segment**. This database contains patterns from a database of 7 outdoor images (classes).
- 159 29. **Thyroid**. The goal in this dataset is to detect if a patient is normal or suffers from hyperthyroidism or hypothyroidism.

30. **Eeg** datasets. As an real word example, consider an EEG dataset described in [26] is used here. The dataset consists of five sets (denoted as Z, O, N, F and S) each containing 100 single-channel EEG segments each having 23.6 sec duration. With different combinations of these sets the produced datasets are Z_F_S, ZO_NF_S, ZONF_S and Z_O_N_F_S.

The results from the experiments are displayed in table 2. It is evident, that the proposed method outperforms the other methods in terms of efficiency in the majority of the objective problems. Of course, the method could be slower than RBF or Neural network due to the usage of Grammatical Evolution, however this increase in time can be significantly reduced with the use of threads.

This software tool produces human readable classification rules in ANSI C++ as well as in Python format. This rules used to classify any classification problem without a priory knowledge about the nature of the problem. The implemented software utilizes the Grammatical Evolution technique to produce the classification rules based on simple BNF grammar. The software is guided by a series of command line options that control many critical options of the underlying method such as the number of chromosomes, the mutation rate etc. Also, the software is designed to be use in multi core computational environments through the public available library of OpenMP. From a extensive series of experiments the proposed method proved to be very reliable on a series of simple and hard classification problems and hence the software can be used in different areas such as physics, chemistry, medicine etc. The user need to provide only the patterns of the classification problem in a simple text format and if it is required a series of command line options. Finally, the software can be easily extended to be more friendly for all users, through a graphical interface.

189 5. Conclusions

A software which implements a method for data classifications was introduced. The method is based on grammatical evolution and the software is designed to be portable. Future versions of the software will include

- Input from various formats such as CSV, Json etc.
- Usage of improvement stopping rules for the genetic algorithm.
 - Additional output formats.
